Abstract

We introduce the gender equality collective action intention (GECAL) scale, and examine its psychometric isomorphism and measurement invariance, using data from university students from 60 countries across 13 world regions ($N = 31,686$). Collective action towards gender equality could be understood as intentional and conscious civic behaviors that are focused on social transformation, questioning power relations and the promotion of gender equality through collective efforts. Collective action is a powerful tool for social change and is fundamental to women and girls' empowerment on a societal level. Although, various instruments to measure collective action intentions have been developed to our knowledge none of the published measures were subject to invariance testing. Our findings indicate that scalar measurement invariance for the GECAL scale allows for comparison of the countries' GECAL mean scores. Moreover, this metric psychometric isomorphism of the GECAL means that we can interpret scores at the country-level (i.e., as a group attribute) conceptually similar to individual attributes. Therefore, our findings provide an important addition to the growing body of literature on gender based collective action by introducing a methodologically sound tool to measure collective action intentions towards gender equality across cultures which we hope can be adopted by future studies.

Keywords: assessment, collective action, isomorphism, measurement invariance, cross-cultural psychology

Acknowledgments

The results presented in this paper are part of the larger project entitled “Towards Gender Harmony” (www.towardsgenderharmony.ug.edu.pl), which involves many wonderful people. Here, we acknowledge our University of Gdańsk Research Assistants Team: Jurand Sobiecki, Agata Bizewska, Mariya Amiroslanova, Aleksandra Głobińska, Andy Milewski, Piotr Piotrowski, Stanislav Romanov, Aleksandra Szulc, and Olga Żychlińska for their assistance with programming the surveys and coordinating the collection of data at all sites. We also send our gratitude to Angela Maitner for her comments on the draft version of the paper.

Funding

This research was funded by a grant from the National Science Centre in Poland (grant number: 2017/26/M/HS6/00360) awarded to Natasza Kosakowska-Berezecka. Data collection by the following researchers was supported by grants as follows: Emma C. O'Connor (grant RL5GM118963 from National Institute of General Medical Sciences of the National Institutes of Health); Angel Gomez (grant RTI2018-093550-B-I00 from the Universidad Nacional de Educación a Distancia, Spain); Sylvie Graf and Martina Hřebíčková (grant 20-01214S from the Czech Science Foundation, and grant RVO: 68081740 from the Institute of Psychology, Czech Academy of Sciences); Teri A. Kirby (grant ES/S00274X/1 from the Economic and Social Research Council); Soledad de Lemus (grant PSI2016-79971-P from Spanish Ministry of Economy and Competitiveness through the excellence); Michelle K. Ryan and Renata Bongiorno (grant ERC-2016-COG 725128 from the European Research Council awarded to Michelle K. Ryan); Marie Gustafsson Sendén, Anna Lindqvist and Emma Renström (grant 2017-00414 from the Swedish Research Council for Health, Working Life, and Welfare); Claudio V. Torres (grant DPI / DIRPE n. 04/2019 from the University of Brasilia).

Measuring Collective Action Intention Toward Gender Equality Across Cultures

“Both men and women should feel free to be sensitive.
Both men and women should feel free to be strong”
Emma Watson, 2014, speaking for the HeForShe alliance

The many years of struggle for women’s rights have resulted in the formal recognition of equality between human beings in the Human Rights Convention of 1945, the International Bill of Human Rights for Women of 1979, as well as multiple conventions and legislation that have tried to address the inequality between men and women over the last 75 years. Many calls for collective actions were directed at the mobilization of the support for gender equality around the world and the inclusion of men and boys as agents of social change. However, to measure willingness to act collectively on behalf of gender equality movements, reliable measures need to be developed.

Currently, little empirical knowledge is available about nation–level factors that correspond to people’s intention to support this forms of collective action. One barrier to this empirical investigation may be the lack of a psychometrically sound and cross-culturally validated measurement scale for assessing intentions to act collectively toward gender equality. That is, there is a need for rigorously tested measures that will be established as cross-culturally valid. Therefore, this paper’s aim is the psychometric evaluation of a scale developed to measure collective action intentions within the gender equality domain.

Collective action (CA) for gender equality might be defined as intentional and conscious civic behaviors that are focused on systemic causes of gender discrimination problems and the promotion of gender equality through collective efforts (see Alisat & Riemer, 2015). Constructing our measure we included items linked to low–level participatory

1 civic action (e.g., involvement with a group, or political party, focused on gender
2 issues/gender equality).
3
4

5
6 Our main goal is to establish a cross-culturally validated measure allowing for multi-
7 nation and multi-level analysis of predictors of collective action intentions to support gender
8 equality. We focused on intentions and not actual behaviors for two main reasons: 1)
9 research shows that intention, although not always strong, is indeed linked to behaviors and
10 actions; 2) much research on intergroup relations and social change focuses on intentions,
11 and links between predictors such as identification, efficacy, and injustice appraisal and both
12 intentions to act and actual behaviors on behalf of the group is well-established (Agostini &
13 van Zomeren, 2021).

22
23
24

25 **Cross-cultural differences in collective action intentions**

26
27
28 Most social psychological models of action imply that experiencing illegitimate
29 negative group-based treatment, along with the resulting feelings of injustice, as well as
30 strong group identification and group efficacy, are key triggers for collective action (Becker
31 & Tausch, 2015). Research on the models of collective actions were conducted mostly with
32 WEIRD (Western, Educated, Industrialized, Rich, Democratic) samples (Henrich et al.,
33 2010). Although, in recent years more studies in different regions of the world have been
34 conducted to explore predictors of CA in various cultural settings (e.g., Fischer et al., 2017;
35 Thomas et al., 2018), there have not been many published attempts to validate measures
36 across many nations.

45
46
47
48
49

50 Cultural dimensions are important in understanding variations of human behaviors.
51 They provide a structured framework for understanding how different cultural values and
52 practices shape actions, attitudes, and communication styles within societies (e.g.
53 individualism vs. collectivism; Hofstede & Minkov, 2010; or tight and loose cultures;
54

63
64
65

1 Gelfand et al., 2011). People in various cultures differ in their tendency to act collectively
2 and in important determinants of such actions. For example, Fischer et al. (2017) show that
3 when faced with hostile sexism, German and Turkish female students choose collective
4 action over indirect conflict management styles (e.g., avoiding confrontation). In contrast,
5 Japanese female students prefer indirect conflict management over collective action. These
6 results suggest that cultural dimensions are important in understanding the motivation to be
7 involved in collective action for gender equality.
8
9

10
11
12
13
14
15
16
17 Additionally, Hu et al. (2014) focused on predictors of collective action based on the
18 individualism-collectivism cultural dimension and the connectivity of the social system. They
19 found that strong motivation to participate and connectivity of the social system play
20 different role in in individualistic vs. collectivist cultures, and call for the inclusion of cultural
21 factors in research on collective action (Hu et al., 2014). In a similar vein, van Zomeren
22 (2016) outlined the need to include a cross-cultural view on collective action. He stressed that
23 to understand collective action, one must consider various layers of determinants, including
24 macro-social factors. Activist actions occur in each social system within a nation-specific
25 cultural norms, laws, and institutions.
26
27
28
29
30
31
32
33
34
35
36
37
38

39 To achieve the above-mentioned goal and include the culture- and nation-level
40 predictors more fully in the research on collective action, we need measurement tools
41 validated across cultures and nations. We set out to address this gap and introduce a
42 questionnaire for cross-cultural and multi-nation comparisons.
43
44
45
46
47

48 **Measurement Invariance**

49

50
51 To be eligible to test differences between countries in intention to act collectively
52 toward gender equality, it is necessary to demonstrate the measurement invariance of the
53 scale used to measure this variable in various cultures. Testing for measurement invariance
54 ensures that any detected differences are genuine and not due to measurement anomalies,
55
56
57
58
59
60
61
62
63
64
65

1 validating the applicability of a measurement tool across multiple groups. Without
2 demonstrating the measurement invariance of the gender equality collective action intention
3 (GECAL) scale across countries, we cannot know with certainty whether the countries being
4 compared are different on a collective action intention or whether/instead, observed score
5 differences result from measurement bias that is related to a person's membership in a
6 country (see Millsap, 2011). Measurement invariance means that the scale's psychometric
7 properties in relation to the measured latent variable are the same across groups. In other
8 words, demonstrating the measurement invariance of the scale in the context of cross-cultural
9 research ensures that the scale measures the same construct consistently across all countries
10 included in the study (Byrne & Matsumoto, 2021; Millsap, 2011; Milfont & Fischer, 2010).
11 We are always obliged to control the correctness of the sources of our inference in
12 multicultural research. Recent studies also show that invariance or non-invariance is not just
13 an issue for cross-cultural comparisons but also for within-cultural comparisons, for instance,
14 when looking at ideological differences (e.g., Republicans, Democrats). Brandt and
15 colleagues (Brandt et al., 2021) have shown that while many effects remain similar, yet
16 reduced sometimes, after accounting for non-invariance and bias, others clearly change,
17 become non-significant, or even flip.

40
41 In the most cases, cross-cultural psychologists report results on three levels of
42 measurement invariance (i.e., configural, metric, and scalar), which are defined by
43 parameters that are constrained to be equal across countries or culture regions (e.g., Rózycka-
44 Tran et al., 2019; Rudnev et al. 2020). The first level, known as configural invariance,
45 requires the same overall factor structure maintained across all national or cultural groups.
46 This means that the pattern of factor loadings is identical, although the actual loadings may
47 differ. The second level, known as metric invariance, requires that the factor loadings are
48 equal across the nations or culture regions. This allows for meaningful comparisons of

64
65

1 relationships between latent constructs and observed variables across groups. Finally, the
2 third level, known as scalar invariance, requires that both factor loadings and item intercepts
3 are equal across the nations or culture regions. Achieving scalar invariance allows researchers
4 to compare average latent scores across countries, as it indicates that the scale operates in the
5 same way across these groups (see Milfont & Fisher, 2010). Partial invariance recognizes that
6 some differences can still allow for meaningful group comparisons (Byrne et al., 1989).
7
8
9
10
11
12
13

14 **Psychometric Isomorphism**

15
16
17 Collective action intention can be considered not only as an individual-level variable but
18 also as a characteristic of a group or culture (i.e., country-level variable). According to the multi-
19 level cross-cultural approach, an individual's experiences resulting from belonging to a given
20 culture has an impact on shaping their opinions, beliefs, and behaviors (Kozlowski & Klein,
21 2000). The intentions towards gender equality collective action shared by group members,
22 regardless of individual differences, determines the existence of this construct at a higher level.
23 We can infer the value of the GECAI at the country level based on aggregated individual scores
24 of countries' citizens. This method is correct, but only if the measure of the given variable
25 demonstrates a psychometric isomorphism that describes the similarity of the construct
26 properties across levels (Tay et al., 2014). Cross-level isomorphism in the context of cross-
27 cultural research implies that a construct at the country level has the same meaning and
28 properties as the same construct at the individual level (Fontaine, 2008; Van de Vijver et al.,
29 2008; Van de Vijver & Watkins, 2006). Demonstrating isomorphism means the same idea at
30 national and individual levels – a country/group can be open to new experiences, just like an
31 individual. Lack of isomorphism means that the variable only exists at one level, for example,,
32 the country level: countries differ in whether they are driving on the left/right side of the street,
33 what a country's GDP is, etc. By establishing the GECAI's isomorphism, it can be assumed that
34 scores collected at the individual level indicate a property attributable to the country with a

64
65

1 similar meaning. Demonstrating isomorphism of the GECAI is essential for the development of a
2 multi-level theory on individual beliefs and behavioral intentions about gender equality.
3

4 Following the proposed simultaneous estimation in testing of psychometric isomorphism
5 by Tay et al. (2014), both configural and metric isomorphism of the GECAI were tested.
6
7 Configural isomorphism means that the same number of factors (weak configural) and the
8 pattern of factor loadings (strong configural) are expected to be similar across levels. In contrast,
9 metric isomorphism means that factor loadings are similar at the individual and county levels. As
10 Tay et al. (2004) argue, “the presence of metric isomorphism would suggest that the
11 interpretation of the common factors is similar across levels” (p. 94).

21 **The Present Research**

22 We set out to develop and validate a cross-culturally sound measure of collective action
23 intention for gender equality. We examined whether the six item Gender Equality Collective
24 Action Intention (GECAI) scale was equivalent across the 60 countries. Our first research
25 question (RQ1) focuses on reliability across countries and aims to verify whether measurement
26 invariance can be established for the GECAI scale.
27
28
29
30
31
32
33
34
35

36 The second research question (RQ2) relates to psychometric isomorphism. Here, we test
37 if we can establish isomorphism of the GECAI scale and if GECAI mean scores can be
38 interpreted at a country–level as a group attribute.
39
40
41
42

43 For the third research question, we investigated whether GECAI mean scores are related
44 to two nation–level variables. First, we analyze the relation between GECAI scores and the
45 Democracy Index (RQ3a), and secondly, its link to the Global Gender Gap Index (GGGI)
46 (RQ3b). The Democracy Index is based on numerous indicators measuring civil liberties,
47 pluralism, and political culture. In 2019, Norway had the highest score, and North Korea had the
48 lowest. The Global Gender Gap Index indexes genders gender disparities across four key
49
50
51
52
53
54
55
56

64
65

1 dimensions (economic participation and opportunity, educational attainment, health and survival,
2 and political empowerment). In 2020, Iceland had the highest score, and Yemen had the lowest.
3

4 Previous results on the above-mentioned relations are mixed. On the one hand, most
5 research has been conducted in the WEIRD countries (Henrich et al., 2010), which, on average,
6 are more democratic and gender egalitarian than non-WEIRD countries. The higher gender
7 parity in these countries is related to past collective actions (e.g., suffragette activism) directed at
8 changing the previous status-quo, and higher scores on the human development index are linked
9 to lower gender inequality (Inglehart & Norris, 2003) and weaker discriminatory beliefs (Napier
10 et al., 2010). Thus, one could assume that people in more democratic and gender-egalitarian
11 countries might be paying more attention to gender issues and are more willing to act against
12 gender discrimination.
13
14
15
16
17
18
19
20
21
22
23
24
25

26 On the other hand, in more gender-egalitarian countries, gender discrimination could be
27 less salient, and the necessity for collective action might be less mobilizing. People in more
28 gender-egalitarian countries might believe that after advances in women's struggle for equality,
29 they now live in a society where sexism and gender discrimination are no longer a problem
30 (Radke et al., 2016). Citizens of these countries might be less focused on gender discrimination,
31 as some level of parity has already been obtained. Moreover, some men may perceive women's
32 empowerment and antidiscrimination efforts as a threat to men (Ruthig et al., 2017).
33
34
35
36
37
38
39
40
41
42
43

44 Because of mixed data and a lack of previous large cross-cultural research on the
45 relationship between willingness to engage in collective action and indexes of democratization of
46 the country and gender equality, we listed RQ3a and RQ3b as exploratory questions.

54 **Participants and Procedure**

55
56
57
58
59
60
61
62
63
64
65

1 Data were collected between January 2018 and February 2020 as part of a large cross-
2 national project (see:
3
4 https://osf.io/fqd4p/?view_only=838833b1be71441694b8b15720b95843). All participants
5
6 were undergraduate students in social sciences who (in most countries) received no
7
8 compensation. IRB approval for each sample was obtained from the researchers' respective
9
10 institutions. Informed consent was obtained from all participants, and participants were
11
12 assured that their data would remain anonymous and confidential. We included data from 60
13
14 countries across 13 world regions ($N = 31,686$). Sample composition and descriptive statistics
15
16 for the GECAI factor score and CFA model fit for each country are included in Table 1.
17
18

19 [Table 1 around here]
20
21

22 **Measures**

23
24 **Gender Equality Collective Action Intentions (GECAI) scale.** We based our items
25
26 on chosen items from the scale by Alisat and Riemer (2015) on environmental actions. The
27
28 GECAI scale contains descriptions of six actions undertaken to support gender equality, such
29
30 as participating in a community event that focused on gender issues or using online tools
31
32 (e.g., Instagram, YouTube) to raise awareness about gender issues/gender equality.
33
34 Participants rated their intention to engage in this type of activity on a seven-point scale
35
36 ranging from 1 = not likely at all to 7 = very likely. Responses for all six items were averaged
37
38 to create a composite measure, in which higher scores reflect a greater intention to engage in
39
40 solidarity-based CA for gender equality. Bilingual scholars used the back-translation
41
42 procedure to create 29 language versions of the scale. All items were translated from English
43
44 to the target language and then back translated. For translations of the GECAI scale in 29
45
46 languages and script, see:

The Democracy Index. This country-level measure is based on numerous indicators measuring civil liberties, pluralism, and political culture. The Economist Intelligence Unit compiles the index measuring the state of democracy for over 160 countries (the Economist Intelligence Unit, 2019). Countries are evaluated from 0 to 10 (with scores from 0 to 4 designating authoritarian regimes and scores from 6.01 to 10 describing flawed and full democracies). In 2020 the highest point was for Norway (9.81) and the lowest for North Korea (1.08).

Global Gender Gap Index (GGGI). We used GGGI scores as a macro-level indicator of gender equality. This index reflects a country's progress towards gender equality on a scale from 0 (disparity) to 1 (parity). GGGI describes gender-gaps in a given country and is based on data from four domains: economic participation and opportunity, educational attainment, health and survival, and political empowerment (World Economic Forum, 2020). In 2020 Iceland was the most gender-equal country in the world (.88), and Yemen was scored the most unequal (.49).

Results

The following sections present the psychometric properties of the GECAI scale by country, measurement invariance testing, psychometric isomorphism testing, and the relationship between GECAI and objective country-level indicators. All calculations and figures were prepared using the R environment (R Core Team, 2020) with the appropriate packages: lavaan (Rosseel, 2012) and nlme (Finch, Bolin & Kelley, 2014).

Item Analyses, Confirmatory Factor Analyses and Reliability of the GECAI Scores across 60 Countries

Before proceeding to primary analyses, we tested the one-factor structure and reliability of the GECAI scale in each national sample. The one-factor GECAI model, tested

1 with confirmatory factor analysis (CFA), was fitted using maximum likelihood estimation
2 and evaluated with the commonly used models' goodness of fit criteria (i.e., CFI > 0.95;
3 RMSEA < 0.08, and SRMR < 0.08) (Brown, 2015). We then estimated the internal
4 consistency reliability of the GECAI measurement using the coefficient ω (McDonald,
5 1999).
6
7
8
9
10

11 As shown in Table 1, the GECAI scale demonstrated an excellent model fit
12 considering the Comparative Fit Index (CFI ranged from 0.95 to 0.99) and the Standardized
13 Root Mean Square Residual (SRMR < 0.050) in all countries. However, when analyzing the
14 Root Mean Square Error of Approximation (RMSEA < 0.080), the fit was generally
15 acceptable but showed exceptions. In the case of 18 countries, the RMSEA was unacceptably
16 high, indicating a discrepancy between different fit indices.
17
18
19
20
21
22
23
24
25

26 The consequences of such a discrepancy are significant. While the model compares
27 favorably against a null model (as indicated by the CFI) and its predicted correlations are
28 close to the observed correlations (as indicated by the SRMR), it may still have issues
29 adequately reproducing the observed data covariance matrix (as indicated by the RMSEA).
30 This issue is further complicated by the simplicity of the model, indicated by a small number
31 of degrees of freedom (df). Simple models with few df can sometimes yield misleading fit
32 indices, as RMSEA can be sensitive to model complexity and might over-penalize simpler
33 models. Kenny et al. (2014) recommend 'not computing the RMSEA for small df models,
34 especially those with small sample sizes, but rather estimating parameters that were not
35 originally specified in the model.'

38
39
40
41
42
43
44
45
46
47
48
49
50

51 Nevertheless, for these 18 countries, the discrepancy between different fit indices
52 suggests that researchers should be cautious about the GECAI model's factor validity. Despite
53 these issues, the GECAI scale demonstrated very good internal consistency reliability in all
54
55

61
62
63
64
65

1 countries, with ω ranging from 0.85 in Nigeria to 0.95 in Northern Ireland, Ukraine, the USA,
2 and Wales.
3

4 Table 2 presents descriptive statistics for the GECAI scale items using the total
5 sample, ICCs (intraclass correlation coefficients) and factor loadings. Observing skewness
6 and kurtosis for scores of individual items did not reveal any significant deviations from the
7 normal distribution. The confirmatory factor analysis results showed that all items strongly
8 explain the GECAI latent variable – the lowest factor loading was 0.72 for item 4 ‘use online
9 tools (e.g., Instagram, YouTube, Facebook, Wikipedia, blogs) to raise awareness about
10 gender issues/gender equality’. Average items’ ICC of 0.10 justifies using a multi-level
11 approach in explaining the GECAI variance (see Dyer et al. 2005).

25

26 **Measurement Invariance of the GECAI Scale across 60 Countries**

27

28 The GECAI scale’s cross-country equivalence (measurement invariance) was tested
29 using multigroup confirmatory factor analysis (MGCFA). First, a configural invariance
30 model was fitted to the data and evaluated with the commonly used models’ goodness of fit
31 criteria (i.e., CFI > 0.95 and RMSEA < 0.08) (Brown, 2015). Second, a metric invariance
32 model, in which the factor loadings are constrained to be equal across countries, was fitted.
33 To identify the metric measurement invariance, it was necessary to show that the model did
34 not fit worse than the configural model. For this purpose, the cut-off criteria for large
35 numbers of samples suggested by Rutkowski and Svetina (2014) were used (i.e., Δ CFI not
36 greater than 0.02 and Δ RMSEA not greater than 0.03). Lastly, a scalar measurement
37 invariance model was fitted, constraining equal factor loadings and item intercepts across all
38 countries. For the evaluation of scalar invariance, we applied stricter cut-off criteria based on
39 Chen (2007), specifically, a Δ CFI not exceeding 0.01 and a Δ RMSEA not exceeding 0.015.

1 partial invariance. Partial invariance is established when the parameters of at least two
2 indicators per construct are equal across groups (Byrne et al., 1989).
3

4 Global fit measures for the measurement invariance models of the GECAI scale are
5 presented in Table 3. As can be seen, the CFIs for the three types of measurement invariance
6 (configural, metric, and scalar) were all above 0.96. These results confirmed metric
7 measurement invariance. However, the model testing scalar invariance fitted significantly
8 worse (according to the adopted cut-off criteria) compared to the model testing metric
9 invariance. Hence, we also fitted the model to accommodate partial scalar invariance,
10 relaxing the requirement for equal intercepts across countries for items #1 and #4. This model
11 was not significantly worse in fit compared to the metric level model, based on the
12 established cut-off criteria.

26
27

28 **Psychometric Isomorphism of the GECAI Scale**

29 To test whether the GECAI demonstrates metric isomorphism across individual and
30 country levels, we followed the steps outlined by Tay et al. (2014). A series of models were
31 fitted to the data using confirmatory factor analyses (CFA) and multi-level confirmatory
32 factor analyses (MCFA). First, the one-factor single-level GECAI model (Model 1) was
33 tested. Second, the strong configural psychometric isomorphism of the one-factor GECAI
34 model (Model 2: one-factor structure at both individual and country levels with the same
35 pattern of factor loadings) was fitted. Third, the strong metric isomorphism of the one-factor
36 GECAI model (Model 3: all loadings constrained to be equal across levels) was tested. Next,
37 the strong metric isomorphism of the one-factor GECAI model controlling basic
38 demographic variables at an individual level, i.e., gender and age (Model 4), was tested.

42
43
44
45
46
47
48
49
50
51
52
53
54

55 As with the measurement invariance testing, it was necessary to demonstrate the
56 configural and metric psychometric isomorphism to show that the subsequent models did not
57
58
59
60
61
62
63
64
65

1 fit worse than the previous models. However, no commonly acceptable cut-off criteria have
2 been established in psychometric isomorphism testing. To assess relative model fit, the BIC
3 (with lower values indicating a better fit) was used, while CFI, RMSEA, and SRMR (both
4 within-group SRMR_W and between-group SRMR_B) were used to determine absolute
5 model fit. Table 4 presents fit statistics for the previously mentioned models. As can be seen,
6 all the first four models had exceptionally good fit measures, indicating that the GECAI
7 demonstrates metric psychometric isomorphism (it has the same factor structure across
8 levels), even when accounting for gender and age. Thus, the interpretation of the GECAI as a
9 country-level variable (not only individual) is reasonable. Figure 1 presents a world map
10 showing mean country-level GECAI factor scores. The countries with the highest level of
11 gender equality collective action intention were Kosovo, India, Nigeria, and Portugal, while
12 the lowest level was observed in Kazakhstan, Denmark, Slovakia, and Czechia.

29 [Figure 1 around here]

30 31 32 33 34 **Correlations of GECAI with Country-Level Indexes**

35
36 The last research question concerned whether GECAI as a country-level variable is
37 related to a country's gender equality, democracy and helping actions. To answer this
38 question, another three multi-level models were defined and tested. Model 5 is a replication
39 of Model 4, except that it additionally includes the Global Gender Gap Index (GGGI) as a
40 country-level GECAI covariate. Model 6 includes the Democracy Index (DI) as a covariate
41 instead of the GGGI¹. As can be seen in Table 4, Models 5 and 6 had very good fit measures.

Discussion

We investigated the measurement invariance and psychometric isomorphism of the gender equality collective action intention scale across 60 countries. The scale turned out to work equivalently in various nations. Comparison of the latent mean scores on the GECAI scale between these nations can be drawn. In the assessment of behavioral intentions directed at working toward societal gender equality, there is a growing awareness of the necessity to consider cultural factors (van Zomeren, 2016). Our study is in line with this reasoning and aims to establishing a valid tool for such cross–cultural comparisons.

Demonstrating the measurement invariance of the tool used, was an important step in the analysis of our study. Although this type of analysis has found more and more applications for many years, it is still not a commonly used practice (Boer et al., 2018). There are also voices aimed at depreciating this stage of multi–group data analysis (including cross–cultural data; Welzel et al., 2021). The analysis of measurement invariance has been used in our approach in a very classic way: we are privileged to work with a scale that, with such an extensive research plane in so many groups, has proved to be scalar invariant. However, it should be emphasized that we are witnessing an intensive development of this segment of psychometric analysis, and where the classical approach does not work, other methods can be used (Fischer et al., 2021; Byrne & Matsumoto, 2021).

Moreover, the GECAI scale demonstrates configural and metric isomorphism across individual and country levels. Thus, the willingness to act collectively toward gender

1 equality, as measured by the GECAI scale, means similar things at the individual and
2 national levels. This is an important result for the assessment of collective action intention, as
3 well as for cross-cultural research on the predictors and correlates of collective action in
4 general. The established isomorphism allows for analyses of correlates between country-
5 level GECAI scores and other country-level variables.
6
7
8
9
10

11 Our results suggest that country-level scores on people's intention to act collectively
12 on behalf of equality are correlated negatively with the democracy index and gender gap
13 index. However, sample bias may play a role here. Specifically, the negative relationship
14 reported here might result from a self-selected sampling bias as we have more data from
15 countries at the middle/higher end of the democracy index. More countries would have to be
16 included – also from the lower end of the democracy index – to establish whether the
17 relationship may actually be curvilinear. It is possible that the pattern of the result might be
18 weaker in countries at the lowest and high ends of this metric (but for vastly different
19 reasons).
20
21
22
23
24
25
26
27
28
29
30
31
32

33 Considering whether the declared willingness to join actions to support gender
34 equality is stronger in countries ranking high vs low in gender equality indices, our findings
35 suggest that the former is more likely to be true –the higher the gender equality of the
36 country, the lower the intention to support gender equality. It is a limitation that our data are
37 correlational, and no casual relations can be established. This notwithstanding, zero-order
38 correlations are insightful, as they point toward barriers to future engagement in actions for
39 gender equality in societies in which gender equality has already been achieved to some
40 extent. Radke and colleagues (2016) argued that one important barrier to engagement on
41 behalf of women's equality is the postfeminist perception of gender equality: The relative
42 success of the women's movements for social change and equality in some countries (mostly
43 in the global North) might influence individuals not to perceive differences of status between
44

65

1 the genders. Many people may believe that sexism and gender-based discrimination is no
2 longer a problem in their country. Thus, the fight for gender equality does not mobilize as
3 many people as it used to. Our cultural cross-cultural research seems to strengthen this
4 assumption by showing a lower readiness to fight for gender equality in more gender-equal
5 countries.
6
7
8
9
10

11 To our knowledge, this study is the first to thoroughly examine and establish a cross-
12 culturally valid measure of collective action intention. Findings are promising and suggest
13 that the GECAI scale can be used for cross-cultural research, with the scale working
14 equivalently in various regions and with psychometric isomorphism established.
15
16
17
18
19

20 Nevertheless, some limitations should be highlighted. First, we only presented a correlation
21 between the GECAI scale and chosen macro-level indicators. As our main goal of this paper
22 is to present and validate the measurement tool, we did not concentrate on exploring various
23 links between the GECAI scale and cultural- and national-level variables. Second, it is
24 important to note that the current sample consisted of a relatively small and specific subgroup
25 of the general population. We based our analyses on university undergraduate students,
26 mostly from psychology and social sciences. Third, although our analyses included data from
27 over 60 nations, there are parts of the world that are underrepresented: There are relatively
28 fewer participants from Africa, the Middle East, and East Asia. Moreover, when it comes to
29 large nations, we did not always have multiple investigators, and in some cases, we based our
30 analyses on one sample from one region.

36
37
38
39
40
41
42
43
44
45
46
47

48 Limitations notwithstanding, our findings provide an important addition to the
49 growing body of literature on collective action. Based on a large dataset covering over 60
50 nations, we introduce a methodologically sound tool that is cross-cultural equivalent in
51 assessing collective action intentions, which we hope can be adopted by future studies on
52 gender equality.

ω = McDonald's omega; CFI = Comparative Fit Index; RMSEA = Root Mean Square Error of Approximation;

SRMR = Standardized Root Mean Squared Residual.

Table 2. Descriptive statistics, ICCs, factor loadings and variances for the GECAI scale items using total sample.

Item	M	SD	Skew.	Kurt.	ICC	λ_s	θ_s
1. become involved with a group (or political party) focused on gender issues/gender equality (e.g., volunteer, summer job, etc.)	3.54	2.03	0.27	-1.20	0.09	0.84	0.29
2. consciously make time to work on gender issues/gender equality (e.g., working part-time for an organization, contributing to raise awareness about gender issues, choosing activities focused on gender issues over other leisure activities)	3.59	1.98	0.25	-1.13	0.11	0.88	0.23
3. participate in a community event which focused on gender issues	3.95	2.02	-0.01	-1.23	0.09	0.88	0.23
4. use online tools (e.g., Instagram, YouTube, Facebook, Wikipedia, Blogs) to raise awareness about gender issues/gender equality	4.04	2.15	-0.05	-1.38	0.10	0.72	0.48
5. participate in an educational event (e.g., workshop) related to gender issues/gender equality	4.19	2.05	-0.16	-1.25	0.09	0.84	0.29
6. spend time working with a group/organization that deals with the connection of gender issues/gender equality to other societal issues such as justice or inequality	3.82	2.01	0.08	-1.21	0.10	0.88	0.22

Note. $N = 31,686$; ICC = Intraclass Correlation Coefficient; λ_s - standardized loading estimate; θ_s - standardized residual estimate.

Table 3. Global fit measures in measurement invariance tests for the GECAI scale.

Level of invariance	χ^2	df	CFI	RMSEA	ΔCFI	$\Delta RMSEA$
Configural invariance (equal form)	2,000.13	540	0.989	0.072	-	-
Metric invariance (equal factor loadings)	2,937.54	835	0.984	0.069	0.005	0.003
Partial scalar invariance (equal intercepts except for items #1 and #4)	4,333.40	1,012	0.975	0.079	0.009	0.010
Scalar invariance (equal intercepts)	5,586.26	1,130	0.967	0.086	0.017	0.017

Notes. 60 countries; χ^2 = chi square; df = degrees of freedom; CFI = Comparative Fit Index; RMSEA = Root Mean Square Error of Approximation.

Table 4. Comparison of multilevel factor analysis models for GECAI.

Model	Fit statistics				
	BIC	CFI	RMSEA	SRMR _w	SRMR _B
Single-level structure (Model 1)	658575	0.993	0.063	0.015	–
Strong configural isomorphism (Model 2)	653183	0.986	0.059	0.016	0.010
Strong metric isomorphism: all loadings constrained to be equal (Model 3)	653167	0.986	0.053	0.016	0.025
With covariate at individual level: Age and Gender (Model 4)	600736 ^a	0.983	0.053	0.019	0.009
With covariate at individual level and at county level: GGGI (Model 5)	600742 ^a	0.983	0.048	0.019	0.019
With covariate at individual level and at county level: DI (Model 6)	600741 ^a	0.983	0.048	0.019	0.023
With covariate at individual level and at county level: WGI (Model 7)	600941 ^a	0.983	0.050	0.019	0.017

Note. $N = 31,686$; ^a $N = 29,306$; BIC = sample-size adjusted Bayesian Information Criterion; CFI = Comparative Fit Index; RMSEA = Root Mean Square Error of Approximation; SRMR_w = Standardized Root Mean Square Residual within covariance matrix; SRMR_B = Standardized Root Mean Square Residual between covariance matrix.

Measuring Collective Action Intention Toward Gender Equality Across Cultures

Supplementary Materials

In response to the reviewers' suggestions, we have conducted additional analyses to further elucidate the relationships and contextual factors relevant to our study on the Gender Equality Collective Action Intention (GECAL) scale across countries. These supplementary materials aim to provide a comprehensive understanding of the association between the GECAL and various country-level and individual-level variables. This detailed examination enhances the robustness and depth of our findings, offering greater insight into the complex dynamics of gender attitudes and beliefs across different cultural contexts.

Correlation between Country-level GECAL and Human Development Index (HDI)

In this section, we present the analysis correlating the country-level GECAL with the Human Development Index (HDI). This comparison provides additional context about a country's development status beyond gender equality and democracy indicators. By integrating HDI, we offer a more nuanced perspective on how human development correlates with gender attitudes and cultural perceptions. To achieve this, we fitted multilevel factor analysis models for GECAL with covariates at both the individual level and the country level: HDI (Model 8; see Table 4 in the main text for previous models). The results of fitting this model are presented in Table S1. Correlations between country-level GECAL and HDI were significant ($p < 0.01$) and negative ($r = -0.66$). As depicted in Figure S1, countries with higher HDI

scores tend to have lower GECAI mean latent scores. These results support the notion that in more developed countries, participants declared less intention to act for gender equality.

Table S1. Multilevel factor analysis model for country-level GECAI and Human Development Index (HDI)

Model	Fit statistics				
	BIC	CFI	RMSEA	SRMR _W	SRMR _B
With covariate at individual level and at county level: HDI (Model 8)	600713	0.983	0.048	0.019	0.015

Note. $N = 29,306$; BIC = sample-size adjusted Bayesian Information Criterion; CFI = Comparative Fit Index; RMSEA = Root Mean Square Error of Approximation; SRMR_W = Standardized Root Mean Square Residual within covariance matrix; SRMR_B = Standardized Root Mean Square Residual between covariance matrix.

Figure S1. Relationship between the Country's HDI and GECAI at the Country-Level.

Analysis of Individual-level Variables Related to Gender Beliefs

This section details the expanded analysis of the relationship between GECAI and various individual-level variables related to gender beliefs. The variables analyzed include: Zero-Sum Perspective toward Gender Status, Hostile Sexism, Benevolent Sexism, and Gender Essentialism. These variables are all related to gender beliefs and attitudes that reflect traditional and often discriminatory views on gender roles. It is expected that there would be a negative correlation between these variables and gender equality collective action intention. This expectation is based on the premise that individuals who hold more traditional, sexist, or essentialist views about gender are less likely to support or engage in actions aimed at promoting gender equality. These attitudes inherently conflict with the goals of gender equality, as they reinforce the status quo and discourage progressive changes in gender dynamics.

Using the data collected in the project, we employed multilevel models to examine these relationships. These models account for the nesting of individuals within countries and partition the variance of the variables into within-country and between-country components. This approach allows for a detailed exploration of how individual beliefs about gender are affected by broader cultural and national contexts.

The results of the multilevel models, in which various individual-level variables related to gender beliefs were predictors of GECAI, are presented in Table S2. As shown, regardless of the country of origin and residence, the stronger the hostile sexism, the lower the willingness to engage in actions supporting gender equality. As predicted, a similar effect was noted for the other gender beliefs. These results can be considered as evidence of the validity of the GECAI measurement, based on the relationship between the measured variable and other theoretically related variables.

Table S2. Multilevel model results: Predictors of GECAI from individual-level gender beliefs

Independent variable	b	β	p-value	R2 (%)	
				Conditional	Marginal
Hostile Sexism	-0.44	-0.32	< 0.01	24	10
Benevolent Sexism	-0.23	-0.17	< 0.01	17	3
Zero-Sum Perspective toward Gender Status	-0.28	-0.16	< 0.01	15	3
Gender Essentialism	-0.31	-0.27	< 0.01	21	7

Note. $N = 31,686$; 60 countries.

Correlation between Country-level GECAI and World Giving Index (WGI)

As an additional indicator of helping behavior, we included the scores from the World Giving Index (WGI). It is an indicator that looks at three facets of giving behaviour in the past month. That is, it is focused on helping a stranger, donating money, and volunteering time to an organization. The WGI aims to provide insight into the scope and nature of giving worldwide, offering a unique perspective on global generosity trends. We acknowledge the relevance of the World Giving Index as a measure of social behavior related to generosity and giving, thus to other (than GECAI) forms of collective action. The highest scoring country in 2020 was Indonesia, and the lowest-scoring country was Japan.

There was no significant relation between GECAI scores on a country level and the World Giving Index ($r = -0.10, p = 0.45$).
